

A-Z

API

Application Program Interfaces are methods for programs to exchange data without the involvement of humans. APIs often involve a schematic description of how the data looks like and where it needs to be sent. Today many APIs are based on [HTTP](#).

Container

Containers are discussed in [lecture 4](#) and provide a way to package an application with its runtime requirement in a self-contained manner. Containers also provide limited security isolation.

Docker

[Docker](#) is one of the earliest modern containerization systems. Docker was largely responsible for promoting the immutable infrastructure concept in containers.

Docker also contains the Docker Swarm orchestrator, a very simple system to manage containers across multiple machines.

Docker is discussed in [lecture 4](#) and [exercise 3](#).
